

HOOKS CANON

2026-03-18

Dexter Hadley, MD/PhD

Hadley Lab CANONIC

Abstract

HOOKS is enforcement at commit time every push validated, every commit ledgered, kernel semantics private.

hadleylab.org Governed Research. Every claim cited.

Contents

- **PRE_COMMIT FIRES EVERYWHERE** pre-commit fires on every governed repo and blocks private kernel semantics outside kernel source.
- **RUNTIME_MAPS_TO_GOV** hooks map each runtime site to its governance scope via CANON.json; magic commit logs the event to the LEDGER.
- **GRADIENT_IS_EVENT** any non-zero score gradient is logged as an event; score change is the ledgered signal. ## Constraints

MUST: pre-commit fires on every governed repo
 MUST: pre-commit blocks private kernel semantics outside kernel source
 MUST: Maps runtime site governance scope via CANON.json
 MUST: Calls magic commit logs to LEDGER
 MUST: Non-zero gradient logged (score change = event)
 MUST: enforce-bloat-gate skips _generated files
 MUST: enforce-bloat-gate blocks boilerplate regressions
 MUST NOT: Skip validation no --no-verify
 MUST NOT: Commit without governance chain resolved
 MUST NOT: Block _generated compiler output fix the compiler
